Error Analysis

High concentration of errors in these dimensions:

- **Structural Integrity** → Very High (all locales)
- **Contains All Requests** → High
- **Style Match** → High
- **Text Included or Requested** → High
- **Captured by Camera** → Medium-High
- **Visual Quality** → Medium

Error Breakdown

Under-penalization is the dominant issue

Consistent across all locales and most dimensions:

- Structural distortions (extra fingers, deformed limbs) marked minor instead of severe
- Missing prompt elements graded as 'captures most' rather than 'not aligned'
- Text errors (spelling, artifacts) identified but not reflected in the final score
- Style mismatches acknowledged but scored too leniently

Trend: Annotators default to conservative grading rather than strict penalization

Guideline misunderstanding is frequent

- Severity thresholds (minor / noticeable / severe) applied inconsistently across locales
- Style categories (Genmoji, Illustration) confused with photorealism or generic AI aesthetics
- Photorealism judged by personal impression rather than objective visual cues
- Flag criteria for trademarked content overlooked
- 2b Text tag marked when no text was requested (N/A should apply)

Trend: Guideline understanding and calibration gap

Inconsistency (over- and under-penalization)

- Structural Integrity: Severely flawed images passed; clean images penalized
- Visual Quality: Blurry subjects missed; clear images downgraded
- Captured by Camera: AI-generated images pass as realistic; genuine photos downgraded
- Flag: Neutral content flagged without justification

Trend: No stable shared calibration — assessments vary by individual

Prompt reading is incomplete

- Specific quantities and attributes missed during review
- Partial fulfillment accepted without checking all prompt constraints
- Text requirements not verified against output

Trend: Visual impression prioritized over systematic prompt verification

Style recognition is shallow

- Style names recognized but not visually validated
- Mixed/hybrid styles not consistently penalized
- Illustration accepted as Genmoji; photorealism confused with style match

Trend: Style evaluation requires calibration that has not been sufficiently instructed

A/B and Preference Ranking errors

- Better-looking image selected instead of the one with fewer prompt failures
- PR rankings contradict dimension-level assessments within the same task

Trend: Limited ability to evaluate comparatively, not just assess in absolute terms.

RCA

- Annotators don't know what minor vs. noticeable vs. severe means — they default to 'safe' (under-penalize)
- Annotators observe randomly instead of following a structured scan order
- Style understanding is low — style names recognized but not visually validated
- Prompts read partially — constraints around objects, actions, text, and style are missed
- No shared calibration anchors — grading varies by individual, not by standard

Action Plan

Structured image scan order

- **Structural Integrity (anatomy, hands, face, objects)**
- **Prompt coverage (all requested elements present and correct)**
- **Style match (analyze carefully, research if not sure)**
- **Text accuracy (presence, spelling, formatting, case)**
- **Visual quality (blurs, stretched/skewed)**
- **Flag**

Severity Calibration

- **Minor → Not noticeable at first glance; only visible on close inspection**
1. Minor issue with the vase handle looking detached from the top section.

2. Minor issue on the smaller chair having only two legs. Not noticed at first glance but only upon closer inspection.

3. Upon closer inspection we can see a slight issue in the shape of the woman's hand (as if merged fingers), and some structural issues with the castle in the background.

- **Noticeable → Visible without zooming; breaks flow but image remains interpretable**
1. The hands don't look like they're holding the glasses. There is also a piece of clothing sticking out from the guy on the right side. These are Noticeable issues.

2. Severe issues: There are severe issues with the finger/hands, and background face, that are upgraded based on latest criteria.

3. The hanger is clearly 'floating' in the air as it's not 'hooked' on the chair. This is a noticeable SI issue.

- **Severe → Immediately apparent; breaks realism or basic form of the subject**
1. Severe SI issues; People's faces are completely distorted.

2. Severe flaws: some ears, eyes, mouths, and tails of the rabbits are very distorted and fused.

3. Severe issues as the person clearly has additional fingers.

Penalty Calibration Examples

- **Incorrect finger count → Severe SI**

Both adults have extra fingers, completely missed by annotators. Severe issue according to the GLs.

- Missing one non-central element → Captures most but not all
1. **Request:** Vector illustration of two people throwing bagels to seagulls on a ferry in Istanbul.
There is no representation of people throwing bagels at the seagulls.

- **Primary object entirely absent → Not aligned**
Request: Golden episcopal rings
Output provides wedding rings and not episcopal rings. This is **not** aligned.

- **Heavy text distortion or spelling errors → Low accuracy (not moderate)**
Requested text "Suadero". The image has major spelling errors.

- **Main subject out of focus → Mild/Noticeable/Severe → Visual Quality issue - blurriness**
 1. When the primary subject shows any blurriness, it should be downgraded in Visual Quality (first image, toast).
If there is no primary subject, the overall image should not contain blurriness or lack of sharpness (2nd image).
If there are some subjects in the image, but the image is captured more as a scenic view, without a single subject in focus, there should be no blurriness in general.

CC

2. Bokeh effect should **not** be marked for blurriness.

Style Recognition

- Do research to understand styles, if not covered by the GLs
- **IMPORTANT:** If the demo samples don't open, click on "+Did Not Load" at the top of the Response evaluation section. Then click on "✓Did Not Load" again. This should reload the demo images.

+ Did Not Load

✓ Did Not Load

- Cover photorealism cues: texture, lighting, shadow, material surface
- Examples shown for comparison

1. The image on the top is somewhat realistic - Partially matches style. The liverwurst looks too smooth and not like something spreadable on bread. The image on the bottom is matching the style.

2. The image on the top is somewhat realistic - Partially Matches Style. The textures appear overly smooth giving it a not very natural look, unlike the case with the image on the top, which is realistic.

3. The following images are clearly NOT photorealistic, as they are AI-generated (image 1), illustration style (image 2) and noir digital illustration (image 3).

Image Comparison Framework

- Pick the LESS wrong image given the dimension evaluations; not the better-looking one
- Which misses fewer prompt elements?
- Which has fewer structural issues?
- Which has better Visual Quality?
- Ensure PR scores are consistent with dimension-level assessments before submitting
